E8 Physics from Cl(8) via Elementary Cellular Automata Bits

John C. Gonsowski*

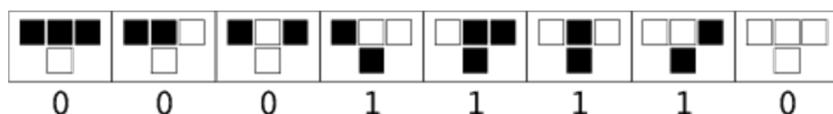

Abstract

In this article, I describe E8 Physics from Cl(8) via pairing elementary cellular automata bits. Smith relates the 256 dimensions of the Cl(8) Clifford Algebra to the 256 rules of Elementary Cellular Automata. The graded dimensions of Cl(8) correspond to graded dimensions of the E8 Lie Algebra used in Smith's physics model. Six Cellular Automata (CA) rules with four one-bits are related to Smith's 8-dim Primitive Idempotent bookended by the single rule with no one-bits and the single rule with all eight bits as ones. The 64 other four one-bit rules are related to E8's 64-dim vector representation used by Smith for a spacetime 8-dim position by 8-dim momentum. The two 28-dim D4 subalgebras of E8 are used for bosons and their ghosts and relate to the CA rules with two one-bits and six one-bits. Paired up CA bits are related to the Cartan subalgebras of these D4s. The two remaining 64-dim spinor representations for E8 are used for eight component fermions/antifermions and relate to the CA rules with one, three, five and seven one-bits.

Keywords: E8 physics, Clifford algebra, Lie algebra, cellular automata, bit, subalgebra.

1. Introduction

Tony Smith [1] relates the 256 dimensions of the Cl(8) Clifford Algebra to the 256 rules of Elementary Cellular Automata [2]. The graded dimensions of Cl(8) correspond to graded dimensions of the E8 Lie Algebra used in Smith's physics model. An 8-dim Primitive Idempotent half spinor along with the 248-dim E8 are embedded in the 256-dim Cl(8). The grading of this Cl(8) is 1 8 28 56 70 56 28 8 1 which sum to the 256 dimensions. This grading gives the quantity of Cellular Automata (CA) rules that have a certain number of one-bits.

The rule above is called rule 30 because the 4 one-bits produce a binary $2+4+8+16=30$. The Cl(8) grading indicates there are 70 rules with 4 of the 8 bits being a one. In other words there

*Correspondence: John C. Gonsowski, Independent Researcher. Email: jcgonsowski@yahoo.com

are 70 ways to place 4 ones in the 8 bits to form a rule. The bits for the rule represent the next state value for the 8 possible values of the current state and the states to the left and right of the current state being evaluated. Via the Cl(8) grading there is one way to have 0 of 8 ones in the rule; 8 ways to have a single one; 28 ways to have two ones; 56 ways to have three ones; 70 ways to have four ones; 56 ways to have five ones; 28 ways to have six ones; 8 ways to have seven ones; and one way to have 8 ones.

2. Relating Basis Vectors to Cellular Automata Bits

Two CA bits are related via Smith's model to the Y and X basis vectors of a YX spatial rotation [3].

Y X

01000000 00001000

Two CA bits are related to the temporal T and spatial Z basis vectors of a Lorentz group TZ boost.

T Z

10000000 00100000

Two CA bits relate to the Conformal group (C) basis vector and an Anti-de Sitter/de Sitter group (A) translation basis vector to form a dilation (CA). This dilation is the Higgs VEV in Smith's physics model.

C A

00000001 00000100

The final two CA bits allow Standard Model Ghosts in Smith's physics using basis vectors M (magenta/minus for strong force anticolor and weak force negative charge) and G (green/greater than zero for strong force color/weak force positive charge). The MG bivector is a propagator phase in Smith's model.

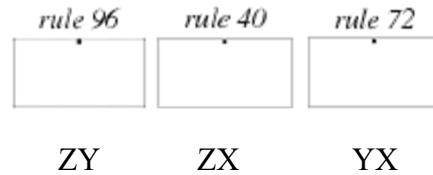

M G

00000010 00010000

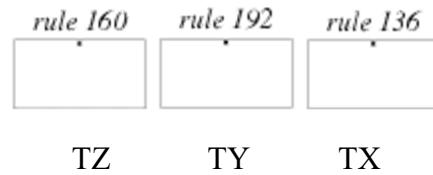

3. Rotations and Boosts

The grading of the 248-dim E8 in Smith's physics model is 28 64 64 64 28. The following bivectors are in the 28s of his E8 grading which match to the 28s in the Cl(8) grading. The E8 28s come from two D4 subalgebras which also relate to the four axes and 24 vertices of a 24-cell, D4's root vector polytope. The 28 Cellular Automata with 2 one-bits and the 28 CA with 6 one-bits will match to these two D4s. Here are the three Lorentz Group gravity spatial rotation [3] bivectors/double one-bits.

6. Ghosts for Rotations and Boosts

The above conformal gravity and Standard Model ghost bivectors fit with the 28 Cellular Automata rules with double one-bits. These 28 CA relate to the first 28 in the E8 and Cl(8) grading. The conformal gravity ghost and Standard Model bivectors fit with the 28 CA with six one-bits. These CA relate to the second 28 in the E8 and Cl(8) grading. The CA with six one-bits are also the CA with double zero-bits. These double zero-bits will be matched to Smith’s D4 conformal gravity ghost and Standard Model bivectors.

Besides using double zero-bits instead of double one-bits, this ghost boson-actual boson bivector mapping also exchanges XYZT vectors with GMAC vectors thus forming a negative transformation [4]. This may relate to how in Smith’s model, the XYZT physical spacetime interacts with the GMAC Kaluza-Klein internal symmetry space. Here are the three Lorentz Group gravity spatial rotation bivectors/double zero-bit ghosts.

There's a pattern where rules (with G vs. M) that slant to the left vs. slanting to the right may relate to charge for the Standard Model bosons and direction change (X vs. Y) for gravity bosons. These reflection transformation [4] bits perhaps relate to how charge, mass, and change of direction are related in Smith's 4-dim Feynman Checkerboard.

9. The Primitive Idempotent and Spacetime Position and Momentum

The grading of the 8-dim Primitive Idempotent (PI) half spinor embedded with E8 in Cl(8) is 1 6 1. In Smith's physics, the PI performs a Standard Model Higgs-like role. This 6-dim PI middle grade is the lower left to upper right diagonal of the 6x6 matrix below. Subtracting the 6 middle grade of the PI from the 70 Cl(8) middle grade gives the 64 middle grade for E8. This 64 middle grade is the position by momentum $8 \times 8 = 64$ -dim vector part of Smith's E8 physics model [5]. This 64-dim part of E8 thus relates to the 4-vector/four one-bit CA rules not used for the 6-dim PI middle grade though the upper left to lower right diagonals of the two 4x4 matrices below form another PI half spinor that is part of the E8 middle grade. Both PI half spinors fit with the 16 Pertti Lounesto terms using basis vectors MGCA_{TYZX} [6]. The position and momentum are 8-dim due to the GMAC Kaluza-Klein internal symmetry space added to the XYZT physical spacetime in Smith's model.

10. Spacetime Components of Fermion Creation Operators

The two remaining 64s in the E8 grading of Smith's model are for 8 spacetime components of fermion creation operators and 8 spacetime components of antifermion creation operators. The E8 64 grading for fermions comes from the 8 Cl(8) vectors plus the 56 Cl(8) 3-vectors. Thus the fermions relate to the Cellular Automata rules with a single one-bit and the rules with three one-bits. Here are the rules for the neutrino creation operator [7].

11. Spacetime Components of Antifermion Creation Operators

The E8 64 grading for antifermions comes from the 8 Cl(8) 7-vectors plus the 56 Cl(8) 5-vectors. Thus the related Cellular Automata rules for the spacetime components of each antifermion creation operator have five one-bits or seven one-bits. Like with the ghost boson to actual boson mapping done earlier, the fermion to antifermion mapping is a negative transformation [4].

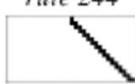

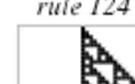

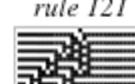

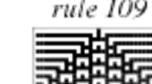

Here are the rules for the antineutrino creation operator.

12. Discussion

The reflection transformation bits mentioned earlier, G vs. M or X vs. Y, may relate to color (with neither/both bits making up the third color) for quarks and antiquarks. The bits may affect slant patterns in general (along with A/Z straight line and C/T periodicity/chaos) for bosons, position-momentum, and fermions/antifermions. Here is the partitioning of rule space [8] associated with this mapping of Cl(8), E8 [9], and Elementary Cellular Automata.

PI: Primitive Idempotent RO: Rotation boson/ghost
 CO: Conformal boson/ghost DI: Dilution boson/ghost
 PR: Propagator Phase Q: Quark creation
 AQ: Antiquark creation P: Positron creation
Wolfram Class 1 Rule Wolfram Class 2 Rule Wolfram Class 3 Rule Wolfram Class 4 Rule
 BO: Boost boson/ghost EW: Electroweak boson/ghost
 GL: Gluon boson/ghost E: Electron creation
 N: Neutrino creation AN: Antineutrino creation
 PM: Position-Momentum

The line of symmetry for the Wolfram Rule Classes (diagonal line from rule 232 to rule 23) has the same rules as the line of symmetry for Rodrigo Obando's [10] rule space partitioning. However, the two lines of symmetry have the rules in different locations on the line. These line of symmetry rules are the rules that are their own negative transformation [4].
